5 Compression

27 October 2023

Sebastian Wild

Learning Outcomes

1. Understand the necessity for encodings and know *ASCII* and *UTF-8 character encodings*.
2. Understand (qualitatively) the *limits of compressibility*.
3. Know and understand the algorithms (encoding and decoding) for *Huffman codes*, *RLE*, *Elias codes*, *LZW*, *MTF*, and *BWT*, including their *properties* like running time complexity.
4. Select and *adapt* (slightly) a *compression pipeline* for specific type of data.

Unit 5: *Compression*

Outline

5 Compression

- 5.1 Context
- 5.2 Character Encodings
- 5.3 Huffman Codes
- 5.4 Entropy
- 5.5 Run-Length Encoding
- 5.6 Lempel-Ziv-Welch
- 5.7 Lempel-Ziv-Welch Decoding
- 5.8 Move-to-Front Transformation
- 5.9 Burrows-Wheeler Transform
- 5.10 Inverse BWT

5.1 Context

Overview

- ▶ Unit 4 & 8: How to *work* with strings
 - ▶ finding substrings
 - ▶ finding approximate matches ~ Unit 8
 - ▶ finding repeated parts ~ Unit 8
 - ▶ ...
 - ▶ assumed character array (random access)!
- ▶ Unit 5 & 6: How to *store/transmit* strings
 - ▶ computer memory: must be binary
 - ▶ how to compress strings (save space)
 - ▶ how to robustly transmit over noisy channels ~ Unit 6

Clicker Question

What compression methods do you know?

→ *sli.do/comp526*

Terminology

- ▶ **source text:** string $S \in \Sigma_S^*$ to be stored / transmitted
 Σ_S is some alphabet
- ▶ **coded text:** encoded data $C \in \Sigma_C^*$ that is actually stored / transmitted
usually use $\Sigma_C = \{0, 1\}$
- ▶ **encoding:** algorithm mapping source texts to coded texts $S \mapsto C$
- ▶ **decoding:** algorithm mapping coded texts back to original source text $C \mapsto S$

Terminology

- ▶ **source text:** string $S \in \Sigma_S^*$ to be stored / transmitted
 Σ_S is some alphabet
- ▶ **coded text:** encoded data $C \in \Sigma_C^*$ that is actually stored / transmitted
usually use $\Sigma_C = \{0, 1\}$
- ▶ **encoding:** algorithm mapping source texts to coded texts
- ▶ **decoding:** algorithm mapping coded texts back to original source text

- ▶ **Lossy vs. Lossless**

- ▶ **lossy compression** can only decode **approximately**;
the exact source text S is lost
 - ▶ **lossless compression** always decodes S exactly

$$S \rightarrow C \rightarrow S'$$

S, S' 'similar'

- ▶ For media files, lossy, logical compression is useful (e. g. JPEG, MPEG)
- ▶ We will concentrate on *lossless* compression algorithms.
These techniques can be used for any application.

What is a good encoding scheme?

- ▶ Depending on the application, goals can be
 - ▶ efficiency of encoding/decoding
 - ▶ resilience to errors/noise in transmission
 - ▶ security (encryption)
 - ▶ integrity (detect modifications made by third parties)
 - ▶ size

What is a good encoding scheme?

- ▶ Depending on the application, goals can be
 - ▶ efficiency of encoding/decoding
 - ▶ resilience to errors/noise in transmission
 - ▶ security (encryption)
 - ▶ integrity (detect modifications made by third parties)
 - ▶ size

size of a string?

$$S \in \Sigma^n \rightarrow n?$$

$$\Sigma_C = \Sigma^n \quad C = S$$

- ▶ Focus in this unit: **size** of coded text

Encoding schemes that (try to) minimize the size of coded texts perform *data compression*.

- ▶ We will measure the compression ratio:
$$\frac{|C| \cdot \lg |\Sigma_C|}{|S| \cdot \lg |\Sigma_S|} \stackrel{\Sigma_C = \{0,1\}}{=} \frac{|C|}{|S| \cdot \lg |\Sigma_S|}$$
 - < 1 means successful compression
 - = 1 means no compression
 - > 1 means “compression” made it bigger!? (yes, that happens ...)

Clicker Question

Do you know what uncomputable problems (halting problem, Post's correspondence problem, ...) are?

- ☐ **A** Sure, I could explain what it is.
- ☐ **B** Heard that in a lecture, but don't quite remember
- ☐ **C** No, never heard of it

→ *sli.do/comp526*

Limits of algorithmic compression

Is this image compressible?

Limits of algorithmic compression

Is this image compressible?

visualization of Mandelbrot set

- ▶ Clearly a complex shape!
 - ▶ Will not compress (too) well using, say, PNG.
 - ▶ but:
 - ▶ completely defined by mathematical formula
- ~> can be generated by a very small program!

Limits of algorithmic compression

Is this image compressible?

visualization of Mandelbrot set

- ▶ Clearly a complex shape!
 - ▶ Will not compress (too) well using, say, PNG.
 - ▶ but:
 - ▶ completely defined by mathematical formula
- ~> can be generated by a very small program!

~> *Kolmogorov complexity*

- ▶ $C =$ any program that outputs S
- self-extracting archives!
- ▶ Kolmogorov complexity = length of smallest such program

Limits of algorithmic compression

Is this image compressible?

visualization of Mandelbrot set

- ▶ Clearly a complex shape!
- ▶ Will not compress (too) well using, say, PNG.
- ▶ but:
 - ▶ completely defined by mathematical formula
- ~> can be generated by a very small program!

~> *Kolmogorov complexity*

- ▶ $C =$ any program that outputs S
 - self-extracting archives!
- ▶ Kolmogorov complexity = length of smallest such program
- ▶ **Problem:** finding smallest such program is *uncomputable*.

~> No optimal encoding algorithm is possible!

~> must be inventive to get efficient methods

What makes data compressible?

- ▶ Lossless compression methods mainly exploit two types of redundancies in source texts:

- 1. uneven character frequencies**

some characters occur more often than others → Part I

- 2. repetitive texts**

different parts in the text are (almost) identical → Part II

What makes data compressible?

- ▶ Lossless compression methods mainly exploit two types of redundancies in source texts:

1. **uneven character frequencies**

some characters occur more often than others → Part I

2. **repetitive texts**

different parts in the text are (almost) identical → Part II

There is no such thing as a free lunch!

Not *everything* is compressible (→ tutorials)

~> focus on versatile methods that often work

Part I

Exploiting character frequencies

5.2 Character Encodings

Character encodings

- ▶ Simplest form of encoding: Encode each source character individually

↪ encoding function $E : \Sigma_S \rightarrow \Sigma_C^*$

- ▶ typically, $|\Sigma_S| \gg |\Sigma_C|$, so need several bits per character
- ▶ for $c \in \Sigma_S$, we call $E(c)$ the codeword of c
- ▶ **fixed-length code:** $|E(c)|$ is the same for all $c \in \Sigma_C$
- ▶ **variable-length code:** not all codewords of same length

Fixed-length codes

- ▶ fixed-length codes are the simplest type of character encodings
- ▶ Example: **ASCII** (American Standard Code for Information Interchange, 1963)

0000000 NUL	0010000 DLE	0100000	0110000 0	1000000 @	1010000 P	1100000 ‘	1110000 p

- ▶ 7 bit per character
- ▶ just enough for English letters and a few symbols (plus control characters)

Fixed-length codes – Discussion

Encoding & Decoding as fast as it gets

Unless all characters equally likely, it wastes a lot of space

inflexible (how to support adding a new character?)

Variable-length codes

- ▶ to gain more flexibility, have to allow different lengths for codewords

- ▶ actually an old idea: **Morse Code**

$$\Sigma_S = \{A, \dots, Z, 0, \dots, 9\}$$

$$\Sigma_C = \{\text{dot}, \text{dash}, \text{pause}\}$$

International Morse Code

1. The length of a dot is one unit.
2. A dash is three units.
3. The space between parts of the same letter is one unit.
4. The space between letters is three units.
5. The space between words is seven units.

Variable-length codes – UTF-8

- ▶ Modern example: UTF-8 encoding of Unicode:

 default encoding for text-files, XML, HTML since 2009

- ▶ Encodes any Unicode character ¹⁵⁰⁰⁰_(137994 as of May 2019, and counting)
- ▶ uses 1–4 bytes (codeword lengths: 8, 16, 24, or 32 bits)
- ▶ Every ASCII character is encoded in 1 byte with leading bit 0, followed by the 7 bits for ASCII
- ▶ Non-ASCII characters start with 1–4 1s indicating the total number of bytes, followed by a 0 and 3–5 bits.

The remaining bytes each start with 10 followed by 6 bits.

Char. number range (hexadecimal)	UTF-8 octet sequence (binary)
0000 0000 – 0000 007F	0xxxxxxx
0000 0080 – 0000 07FF	<u>11</u> 0xxxxx 10xxxxxx
0000 0800 – 0000 FFFF	<u>111</u> 0xxxx 10xxxxxx 10xxxxxx
0001 0000 – 0010 FFFF	<u>1111</u> 0xxx <u>10</u> xxxxxx 10xxxxxx 10xxxxxx

 For English text, most characters use only 8 bit,
but we can include any Unicode character, as well.

Pitfall in variable-length codes

- Suppose we have the following code:

c	a	n	b	s
$E(c)$	0	10	110	100
- Happily encode text $S = \text{banana}$ with the coded text $C = \underline{1100}\underline{100}\underline{100}$

b
a
n
a
n
a

Pitfall in variable-length codes

- Suppose we have the following code:
- | | | | | |
|--------|---|----|-----|-----|
| c | a | n | b | s |
| $E(c)$ | 0 | 10 | 110 | 100 |
- Happily encode text $S = \text{banana}$ with the coded text $C = \underline{1100}\underline{100}\underline{100}$
- b a n a n a

⚡ $C = 1100100100$ decodes **both** to banana and to bass: $\underline{1100}\underline{100}\underline{100}$

b a s s

↪ not a valid code ... (cannot tolerate ambiguity)

but how should we have known?

Code tries

from before
 $n = 10$
 $s = 100$

- From now on only consider prefix-free codes E :
 $E(c)$ is not a prefix of $E(c')$ for any $c, c' \in \Sigma_S$.

► Example:

c	A	E	N	O	T	\sqcup
$E(c)$	01	101	001	100	11	000

Any prefix-free code corresponds to a **(code) trie**:

see also Unit 8

- binary tree
- one **leaf** for each characters of Σ_S
- path from root to leaf = codeword
 left child = 0; right child = 1

- Example for using the code trie:

- Encode AN \sqcup ANT

01001000010011

- Decode 111000001010111

TG \sqcup EAT

Code tries

- ▶ From now on only consider prefix-free codes E :

$E(c)$ is not a prefix of $E(c')$ for any $c, c' \in \Sigma_S$.

▶ **Example:**

c	A	E	N	O	T	\sqcup
$E(c)$	01	101	001	100	11	000

Any prefix-free code corresponds to a **(code) trie**:

- ▶ binary tree
- ▶ one **leaf** for each characters of Σ_S
- ▶ path from root to leaf = codeword
left child = 0; right child = 1

- ▶ Example for using the code trie:
 - ▶ Encode $AN_{\sqcup}ANT \rightarrow 010010000100111$
 - ▶ Decode $1110000001010111 \rightarrow T0_{\sqcup}EAT$

Who decodes the decoder?

- ▶ Depending on the application, we have to **store/transmit** the **used code**!
- ▶ We distinguish:
 - ▶ **fixed coding**: code agreed upon in advance, not transmitted (e. g., Morse, UTF-8)
 - ▶ **static coding**: code depends on message, but stays same for entire message;
it must be transmitted (e. g., Huffman codes → next)
 - ▶ **adaptive coding**: code depends on message and changes during encoding;
implicitly stored withing the message (e. g., LZW → below)

5.3 Huffman Codes

Character frequencies

- **Goal:** Find character encoding that produces short coded text
- Convention here: fix $\Sigma_C = \{0, 1\}$ (binary codes), abbreviate $\Sigma = \Sigma_S$,
- **Observation:** Some letters occur more often than others.

Typical English prose:

e	12.70%	██████	d	4.25%	██	p	1.93%	█
t	9.06%	████	l	4.03%	██	b	1.49%	█
a	8.17%	████	c	2.78%	█	v	0.98%	█
o	7.51%	████	u	2.76%	█	k	0.77%	█
i	6.97%	████	m	2.41%	█	j	0.15%	
n	6.75%	████	w	2.36%	█	x	0.15%	
s	6.33%	████	f	2.23%	█	q	0.10%	
h	6.09%	████	g	2.02%	█	z	0.07%	
r	5.99%	████	y	1.97%	█			

~> Want shorter codes for more frequent characters!

Huffman coding

e. g. frequencies / probabilities

▶ **Given:** Σ and weights $w : \Sigma \rightarrow \mathbb{R}_{\geq 0}$

▶ **Goal:** prefix-free code E (= code trie) for Σ that minimizes coded text length

i. e., a code trie minimizing
$$\sum_{c \in \Sigma} \underbrace{w(c)}_{\text{weight of } c} \cdot \underbrace{|E(c)|}_{\text{length of codeword for } c}$$

Huffman coding

e. g. frequencies / probabilities

- ▶ **Given:** Σ and weights $w : \Sigma \rightarrow \mathbb{R}_{\geq 0}$
- ▶ **Goal:** prefix-free code E (= code trie) for Σ that minimizes coded text length

i. e., a code trie minimizing $\sum_{c \in \Sigma} w(c) \cdot |E(c)|$

- ▶ Let's abbreviate $|S|_c = \text{\#occurrences of } c \text{ in } S$
- ▶ If we use $w(c) = |S|_c$,
this is the character encoding with smallest possible $|C|$

↪ best possible *character-wise* encoding
prefix-free

- ▶ Quite ambitious! *Is this efficiently possible?*

Huffman's algorithm

- ▶ Actually, yes! A greedy/myopic approach succeeds here.

Huffman's algorithm:

1. Find two characters a , b with lowest weights.
 - ▶ We will encode them with the same prefix, plus one distinguishing bit, i. e., $E(a) = u0$ and $E(b) = u1$ for a bitstring $u \in \{0, 1\}^*$ (u to be determined)
 2. (Conceptually) replace a and b by a single character " \boxed{ab} " with $w(\boxed{ab}) = w(a) + w(b)$.
 3. Recursively apply Huffman's algorithm on the smaller alphabet. This in particular determines $u = E(\boxed{ab})$.
- ▶ efficient implementation using a (min-oriented) priority queue
 - ▶ start by inserting all characters with their weight as key
 - ▶ step 1 uses two deleteMin calls
 - ▶ step 2 inserts a new character with the sum of old weights as key

Huffman's algorithm – Example

► Example text: $S = \text{LOSSLESS}$ $\rightsquigarrow \Sigma_S = \{E, L, O, S\}$

► Character frequencies: $E : 1, \quad L : 2, \quad O : 1, \quad S : 4$

Huffman's algorithm – Example

► Example text: $S = \text{LOSSLESS}$ $\rightsquigarrow \Sigma_S = \{E, L, O, S\}$

► Character frequencies: $E : 1, \quad L : 2, \quad O : 1, \quad S : 4$

Huffman's algorithm – Example

► Example text: $S = \text{LOSSLESS}$ $\rightsquigarrow \Sigma_S = \{E, L, O, S\}$

► Character frequencies: $E : 1, \quad L : 2, \quad O : 1, \quad S : 4$

Huffman's algorithm – Example

► Example text: $S = \text{LOSSLESS}$ $\rightsquigarrow \Sigma_S = \{E, L, O, S\}$

► Character frequencies: $E : 1, \quad L : 2, \quad O : 1, \quad S : 4$

$$E(L) = 01$$

Huffman's algorithm – Example

► Example text: $S = \text{LOSSLESS}$ $\rightsquigarrow \Sigma_S = \{E, L, O, S\}$

► Character frequencies: $E : 1, \quad L : 2, \quad O : 1, \quad S : 4$

\rightsquigarrow *Huffman tree* (code trie for Huffman code)

Huffman's algorithm – Example

► Example text: $S = \text{LOSSLESS}$ $\rightsquigarrow \Sigma_S = \{E, L, O, S\}$

► Character frequencies: $E : 1, \quad L : 2, \quad O : 1, \quad S : 4$

\rightsquigarrow *Huffman tree* (code trie for Huffman code)

LOSSLESS \rightarrow 01001110100011

compression ratio: $\frac{14}{8 \cdot \log 4} = \frac{14}{16} \approx 88\%$

(but: much slower code)

Huffman tree – tie breaking

- ▶ The above procedure is ambiguous:
 - ▶ which characters to choose when weights are equal?
 - ▶ which subtree goes left, which goes right?

- ▶ For COMP 526: always use the following rule:

1. To break ties when selecting the two characters, first use the smallest letter according to the alphabetical order, or the tree containing the smallest alphabetical letter.
2. When combining two trees of different values, place the lower-valued tree on the left (corresponding to a 0-bit).
3. When combining trees of equal value, place the one containing the smallest letter to the left.

~> practice in tutorials

Encoding with Huffman code

- ▶ The overall encoding procedure is as follows:
 - ▶ **Pass 1:** Count character frequencies in S
 - ▶ Construct Huffman code E (as above)
 - ▶ Store the Huffman code in C (details omitted) *← canonicaize*
 - ▶ **Pass 2:** Encode each character in S using E and append result to C
- ▶ Decoding works as follows:
 - ▶ Decode the Huffman code E from C . (details omitted)
 - ▶ Decode S character by character from C using the code trie.
- ▶ Note: Decoding is much simpler/faster!

Huffman code – Optimality

Theorem 5.1 (Optimality of Huffman's Algorithm)

Given Σ and $w : \Sigma \rightarrow \mathbb{R}_{\geq 0}$, Huffman's Algorithm computes codewords $E : \Sigma \rightarrow \{0, 1\}^*$ with minimal expected codeword length $\ell(E) = \sum_{c \in \Sigma} w(c) \cdot |E(c)|$ among all prefix-free codes for Σ . ◀

Huffman code – Optimality

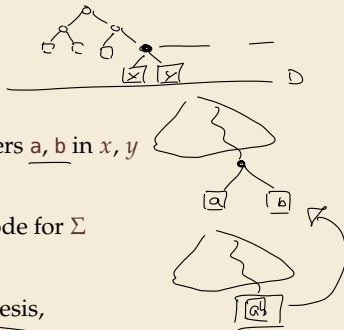

Theorem 5.1 (Optimality of Huffman's Algorithm)

Given Σ and $w : \Sigma \rightarrow \mathbb{R}_{\geq 0}$, Huffman's Algorithm computes codewords $E : \Sigma \rightarrow \{0,1\}^*$ with minimal expected codeword length $\ell(E) = \sum_{c \in \Sigma} w(c) \cdot |E(c)|$ among all prefix-free codes for Σ .

IB: $\sigma \leq 2$ only one possible $\ell(E)$ ✓

Proof sketch: by induction over $\sigma = |\Sigma|$ IS: $\sigma \geq 3$

- ▶ Given any optimal prefix-free code E^* (as its code trie).
 - ▶ code trie $\rightsquigarrow \exists$ two sibling leaves x, y at largest depth D
 - ▶ swap characters in leaves to have two lowest-weight characters a, b in x, y (that can only make ℓ smaller, so still optimal)
 - ▶ any optimal code for $\Sigma' = \Sigma \setminus \{a, b\} \cup \{\overline{ab}\}$ yields optimal code for Σ by replacing leaf \overline{ab} by internal node with children a and b .
- \rightsquigarrow recursive call yields optimal code for Σ' by inductive hypothesis, so Huffman's algorithm finds optimal code for Σ .

5.4 Entropy

Entropy

Definition 5.2 (Entropy)

Given probabilities p_1, \dots, p_n (for outcomes $1, \dots, n$ of a random variable), the *entropy* of the distribution is defined as

$$\mathcal{H}(p_1, \dots, p_n) = - \sum_{i=1}^n p_i \lg p_i = \sum_{i=1}^n p_i \lg \left(\frac{1}{p_i} \right)$$

$$0 \leq \mathcal{H}(p_1, \dots, p_n) \leq \lg n$$

maximal if $p_i = \frac{1}{n}$

Entropy

Definition 5.2 (Entropy)

Given probabilities p_1, \dots, p_n (for outcomes $1, \dots, n$ of a random variable), the *entropy* of the distribution is defined as

$$\mathcal{H}(p_1, \dots, p_n) = - \sum_{i=1}^n p_i \lg p_i = \sum_{i=1}^n p_i \lg \left(\frac{1}{p_i} \right)$$

- ▶ entropy is a **measure of information** content of a distribution
 - ▶ “20 Questions on $[0, 1)$ ”: Land inside my interval by halving.

Entropy

Entropy

Definition 5.2 (Entropy)

Given probabilities p_1, \dots, p_n (for outcomes $1, \dots, n$ of a random variable), the *entropy* of the distribution is defined as

$$\mathcal{H}(p_1, \dots, p_n) = - \sum_{i=1}^n p_i \lg p_i = \sum_{i=1}^n p_i \lg \left(\frac{1}{p_i} \right)$$

- entropy is a **measure of information** content of a distribution
 - “20 Questions on $[0, 1)$ ”: Land inside my interval by halving.

~ Need to cut $[0, 1)$ in half $\lg(1/p_i)$ times

► more precisely: the expected number of bits (Yes/No questions) required to nail down the random value

Entropy and Huffman codes

- ▶ would ideally encode value i using $\lg(1/p_i)$ bits

not always possible; cannot use codeword of 1.5 bits . . .

not as length of single codeword that is;
but can be possible *on average*!

Entropy and Huffman codes

- would ideally encode value i using $\lg(1/p_i)$ bits

not as length of single codeword that is;
but can be possible *on average*!

not always possible; cannot use codeword of 1.5 bits ... but:

Theorem 5.3 (Entropy bounds for Huffman codes)

For any probabilities p_1, \dots, p_σ for $\Sigma = \{a_1, \dots, a_\sigma\}$, the Huffman code E for Σ with weights $p(a_i) = p_i$ satisfies $\mathcal{H} \leq \ell(E) \leq \mathcal{H} + 1$ where $\mathcal{H} = \mathcal{H}(p_1, \dots, p_\sigma)$. ◀

Entropy and Huffman codes

- would ideally encode value i using $\lg(1/p_i)$ bits

not as length of single codeword that is;
but can be possible *on average*!

not always possible; cannot use codeword of 1.5 bits ... but:

Theorem 5.3 (Entropy bounds for Huffman codes)

For any probabilities p_1, \dots, p_σ for $\Sigma = \{a_1, \dots, a_\sigma\}$, the Huffman code E for Σ with weights $p(a_i) = p_i$ satisfies $\mathcal{H} \leq \ell(E) \leq \mathcal{H} + 1$ where $\mathcal{H} = \mathcal{H}(p_1, \dots, p_\sigma)$.

Proof sketch:

- $\ell(E) \geq \mathcal{H}$

Any prefix-free code E induces weights $q_i = 2^{-|E(a_i)|}$.

By *Kraft's Inequality*, we have $q_1 + \dots + q_\sigma \leq 1$.

Hence we can apply *Gibb's Inequality* to get

$$\mathcal{H} = \sum_{i=1}^{\sigma} p_i \lg\left(\frac{1}{p_i}\right) \leq \sum_{i=1}^{\sigma} p_i \lg\left(\frac{1}{q_i}\right) = \ell(E).$$

Entropy and Huffman codes [2]

Proof sketch (continued):

- $\ell(E) \leq \mathcal{H} + 1$

Set $q_i = 2^{-\lceil \lg(1/p_i) \rceil}$. We have $\sum_{i=1}^{\sigma} p_i \lg\left(\frac{1}{q_i}\right) = \sum_{i=1}^{\sigma} p_i \underbrace{\lceil \lg(1/p_i) \rceil}_{\leq \lg(1/p_i) + 1} \leq \mathcal{H} + 1$.

We construct a code E' for Σ with $|E'(a_i)| \leq \lg(1/q_i)$ as follows;

w.l.o.g. assume $q_1 \leq q_2 \leq \dots \leq q_{\sigma}$

- If $\sigma = 2$, E' uses a single bit each.

Here, $q_i \leq 1/2$, so $\lg(1/q_i) \geq 1 = |E'(a_i)|$ ✓

- If $\sigma \geq 3$, we merge a_1 and a_2 to $\boxed{a_1 a_2}$, assign it weight $2q_2$ and recurse.

If $q_1 = q_2$, this is like Huffman; otherwise, q_1 is a unique smallest value and

$q_1 + q_2 + \dots + q_{\sigma} \leq 1$.

By the inductive hypothesis, we have $|E'(\boxed{a_1 a_2})| \leq \lg\left(\frac{1}{2q_2}\right) = \lg\left(\frac{1}{q_2}\right) - 1$.

By construction, $|E'(a_1)| = |E'(a_2)| = |E'(\boxed{a_1 a_2})| + 1$, so $|E'(a_1)| \leq \lg(1/q_1)$ and $|E'(a_2)| \leq \lg(1/q_2)$.

By optimality of E , we have $\ell(E) \leq \ell(E') \leq \sum_{i=1}^{\sigma} p_i \lg\left(\frac{1}{q_i}\right) \leq \mathcal{H} + 1$.

$$\sum p_i |E(a_i)|$$

Clicker Question

When does Huffman coding yield more efficient compression than a fixed-length character encoding?

- ☐ A always
- ☐ B when $\mathcal{H} \approx \lg(\sigma)$
- ☐ C when $\mathcal{H} < \lg(\sigma)$
- ☐ D when $\mathcal{H} < \lg(\sigma) - 1$
- ☐ E when $\mathcal{H} \approx 1$

→ sli.do/comp526

Clicker Question

When does Huffman coding yield more efficient compression than a fixed-length character encoding?

- ☒ A always ✓
- ☐ B ~~when $\mathcal{H} \approx \lg(\sigma)$~~
- ☐ C ~~when $\mathcal{H} < \lg(\sigma)$~~
- ☒ D when $\mathcal{H} < \lg(\sigma) - 1$ ✓
- ☐ E ~~when $\mathcal{H} \approx 1$~~

Empirical Entropy

- ▶ Theorem 5.3 works for *any* character *probabilities* p_1, \dots, p_σ
... but we only have a string S ! (nothing random about it!)

Empirical Entropy

- ▶ Theorem 5.3 works for *any* character *probabilities* p_1, \dots, p_σ
... but we only have a string S ! (nothing random about it!)

use relative frequencies: $p_i = \frac{|S|_{a_i}}{|S|} = \frac{\text{\#occurences of } a_i \text{ in string } S}{\text{length of } S}$

- ▶ Recall: For $S[0..n)$ over $\Sigma = \{a_1, \dots, a_\sigma\}$,
length of Huffman-coded text is

$$|C| = \sum_{i=1}^{\sigma} |S|_{a_i} \cdot |E(a_i)| = n \sum_{i=1}^{\sigma} \overset{=p_i}{\frac{|S|_{a_i}}{n}} \cdot |E(a_i)| = n \underline{\ell(E)}$$

~> Theorem 5.3 tells us rather precisely how well Huffman compresses:

$$\mathcal{H}_0(S) \cdot n \leq \underline{|C|} \leq (\mathcal{H}_0(S) + 1)n$$

- ▶ $\underline{\mathcal{H}_0(S)} = \mathcal{H}\left(\frac{|S|_{a_1}}{n}, \dots, \frac{|S|_{a_\sigma}}{n}\right) = \sum_{i=1}^{\sigma} \frac{n}{|S|_{a_i}} \log_2\left(\frac{|S|_{a_i}}{n}\right)$ is called the *empirical entropy* of S ↖ zero-th order empirical entropy

Huffman coding – Discussion

- ▶ running time complexity: $O(\sigma \log \sigma)$ to construct code
 - ▶ build PQ + $\sigma \cdot (2 \text{ deleteMins and } 1 \text{ insert})$
 - ▶ can do $\Theta(\sigma)$ time when characters already sorted by weight
 - ▶ time for encoding text (after Huffman code done): $O(n + |C|)$
- ▶ many variations in use (tie-breaking rules, estimated frequencies, adaptive encoding, ...)

Huffman coding – Discussion

- ▶ running time complexity: $O(\sigma \log \sigma)$ to construct code
 - ▶ build PQ + $\sigma \cdot (2 \text{ deleteMins and } 1 \text{ insert})$
 - ▶ can do $\Theta(\sigma)$ time when characters already sorted by weight
 - ▶ time for encoding text (after Huffman code done): $O(n + |C|)$
- ▶ many variations in use (tie-breaking rules, estimated frequencies, adaptive encoding, ...)

optimal prefix-free character encoding

very fast decoding

needs 2 passes over source text for encoding

- ▶ one-pass variants possible, but more complicated

have to store code alongside with coded text

Part II

Compressing repetitive texts

5.5 Run-Length Encoding

Run-Length encoding

- ▶ simplest form of repetition: *runs* of characters

[illegible]

^same character repeated

- ▶ here: only consider $\Sigma_S = \{0, 1\}$ (work on a binary representation)
 - ▶ can be extended for larger alphabets

Run-Length encoding

- ▶ simplest form of repetition: *runs* of characters

[illegible]

^same character repeated

- ▶ here: only consider $\Sigma_S = \{0, 1\}$ (work on a binary representation)
 - ▶ can be extended for larger alphabets

→ run-length encoding (RLE):

use runs as phrases: $S = \underbrace{00000}_{5 \times 0} \underbrace{111}_{3 \times 1} \underbrace{0000}_{4 \times 0}$

Run-Length encoding

- ▶ simplest form of repetition: *runs* of characters

[illegible]

^same character repeated

- ▶ here: only consider $\Sigma_S = \{0, 1\}$ (work on a binary representation)
 - ▶ can be extended for larger alphabets

→ run-length encoding (RLE):

use runs as phrases: $S = \underbrace{00000}_{\text{0}} \underbrace{111}_{\text{1}} \underbrace{0000}_{\text{0}}$

⇒ We have to store

- ▶ the first bit of S (either 0 or 1)
- ▶ the length of each subsequent run
- ▶ Note: don't have to store bit for later runs since they must alternate.

- Example becomes: 0, 5, 3, 4

$$\Sigma_c = \{0, 1\}$$

Run-Length encoding

- ▶ simplest form of repetition: *runs* of characters

[illegible]

^same character repeated

- ▶ here: only consider $\Sigma_S = \{0, 1\}$ (work on a binary representation)
 - ▶ can be extended for larger alphabets

→ run-length encoding (RLE):

use runs as phrases: $S = \underbrace{00000}_{\text{run 1}} \underbrace{111}_{\text{run 2}} \underbrace{0000}_{\text{run 3}}$

⇒ We have to store

- ▶ the first bit of S (either 0 or 1)
- ▶ the length of each subsequent run
- ▶ Note: don't have to store bit for later runs since they must alternate.

- Example becomes: 0, 5, 3, 4

- **Question:** How to encode a run length k in binary? (k can be arbitrarily large!)

Clicker Question

How would you encode a string that can be arbitrarily long?

- ① start with length, then as many chars
- ② null-terminated string `'\0'`

→ sli.do/comp526

Elias codes

- ▶ Need a *prefix-free encoding* for $\mathbb{N} = \{1, 2, 3, \dots, \}$
 - ▶ must allow arbitrarily large integers
 - ▶ must know when to stop reading

Elias codes

- ▶ Need a *prefix-free encoding* for $\mathbb{N} = \{1, 2, 3, \dots, \}$

- ▶ must allow arbitrarily large integers
 - ▶ must know when to stop reading

- ▶ But that's simple! Just use **unary encoding**!

$7 \mapsto 00000001$ $3 \mapsto 0001$ $0 \mapsto 1$ $30 \mapsto 00000000000000000000000000000001$

What is the **second-to-last line** of the poem to the left?

→ sli.do/comp526

Lempel-Ziv Compression

- ▶ Huffman and RLE mostly take advantage of frequent or repeated *single characters*.
- ▶ **Observation:** Certain *substrings* are much more frequent than others.
 - ▶ in English text: the, be, to, of, and, a, in, that, have, I
 - ▶ in HTML: “<a href”, “<img src”, “
”
- ▶ **Lempel-Ziv** stands for family of *adaptive* compression algorithms.
 - ▶ **Idea:** store repeated parts by reference!
 - ~> each codeword refers to
 - ▶ either a single character in Σ_S ,
 - ▶ or a *substring* of S (that both encoder and decoder have seen before).
 - ▶ Variants of Lempel-Ziv compression
 - ▶ “LZ77” Original version (sliding window, overlapping phrases)
Derivatives: LZSS, LZFG, LZRW, LZP, DEFLATE, ...
DEFLATE used in (pk)zip, gzip, PNG
 - ▶ “LZ78” Second version (whole-phrase references)
Derivatives: LZW, LZMW, LZAP, LZY, ...
LZW used in compress, GIF

Lempel-Ziv-Welch

- ▶ here: *Lempel-Ziv-Welch (LZW)* (arguably the “cleanest” variant of Lempel-Ziv)
- ▶ *variable-to-fixed* encoding
 - ▶ all codewords have k bits (typical: $k = 12$) \rightsquigarrow fixed-length
 - ▶ but they represent a variable portion of the source text!

- ▶ *variable-to-fixed encoding*
 - ▶ all codewords have k bits (typical: $k = 12$) \rightsquigarrow fixed-length
 - ▶ but they represent a variable portion of the source text!
- ▶ maintain a **dictionary** D with 2^k entries \rightsquigarrow codewords = indices in dictionary
 - ▶ initially, first $|\Sigma_S|$ entries encode single characters (rest is empty)
 - ▶ **add** a new entry to D **after each step**:
 - ▶ **Encoding**: after encoding a substring x of S , add xc to D where c is the character that follows x in S .

\rightsquigarrow new codeword in D

- ▶ D actually stores codewords for x and c , not the expanded string

LZW encoding – Example

Input: YO!_YOU!_YOUR_YOYO!

Σ_S = ASCII character set (0–127)

$C =$

LZW encoding – Code

```
1 procedure LZWencode( $S[0..n]$ )
2    $x := \varepsilon$  // previous phrase, initially empty
3    $C := \varepsilon$  // output, initially empty
4    $D :=$  dictionary, initialized with codes for  $c \in \Sigma_S$  // stored as trie ( $\rightsquigarrow$  Unit 8)
5    $k := |\Sigma_S|$  // next free codeword
6   for  $i := 0, \dots, n - 1$  do
7      $c := S[i]$ 
8     if  $D.\text{containsKey}(xc)$  then
9        $x := xc$ 
10    else
11       $C := C \cdot D.\text{get}(x)$  // append codeword for  $x$ 
12       $D.\text{put}(xc, k)$  // add  $xc$  to  $D$ , assigning next free codeword
13       $k := k + 1$ ;  $x := c$ 
14  end for
15   $C := C \cdot D.\text{get}(x)$ 
16  return  $C$ 
```

5.7 Lempel-Ziv-Welch Decoding

LZW decoding

- Decoder has to replay the process of growing the dictionary!

~> **Decoding:**

after decoding a substring y of S , add xc to D ,
where x is previously encoded/decoded substring of S ,
and $c = y[0]$ (first character of y)

~> Note: only start adding to D after *second* substring of S is decoded

LZW decoding – Example

- ▶ Same idea: build dictionary while reading string.
- ▶ Example: 67 65 78 32 66 129 133

$D =$

Code #	String
...	
32	□
...	
...	
65	A
66	B
67	C
...	
78	N
...	
83	S
...	

input	decodes to	Code #	String (human)	String (computer)

LZW decoding – Bootstrapping

- ▶ example: Want to decode 133, but not yet in dictionary!

decoder is “one step behind” in creating dictionary

LZW decoding – Bootstrapping

► example: Want to decode 133, but not yet in dictionary!

decoder is “one step behind” in creating dictionary

↪ problem occurs if *we want to use a code* that we are *just about to build*.

LZW decoding – Bootstrapping

- ▶ example: Want to decode 133, but not yet in dictionary!

decoder is “one step behind” in creating dictionary

↪ problem occurs if *we want to use a code* that we are *just about to build*.

- ▶ But then we actually know what is going on!
 - ▶ Situation: decode using k in the step that will define k .
 - ▶ decoder knows last phrase x , needs phrase $y = D[k] = xc$.

1. en/decode x .

2. store $D[k] := xc$

3. next phrase y equals $D[k]$

↪ $D[k] = xc = x \cdot x[0]$ (all known)

LZW decoding – Code

```
1 procedure LZWdecode( $C[0..m]$ )
2    $D :=$  dictionary  $[0..2^d) \rightarrow \Sigma_S^+$ , initialized with codes for  $c \in \Sigma_S$  // stored as array
3    $k := |\Sigma_S|$  // next unused codeword
4    $q := C[0]$  // first codeword
5    $y := D[q]$  // lookup meaning of  $q$  in  $D$ 
6    $S := y$  // output, initially first phrase
7   for  $j := 1, \dots, m - 1$  do
8      $x := y$  // remember last decoded phrase
9      $q := C[j]$  // next codeword
10    if  $q == k$  then
11       $y := x \cdot x[0]$  // bootstrap case
12    else
13       $y := D[q]$ 
14       $S := S \cdot y$  // append decoded phrase
15       $D[k] := x \cdot y[0]$  // store new phrase
16       $k := k + 1$ 
17  end for
18  return  $S$ 
```

LZW decoding – Example continued

 $\rightsquigarrow D[k] = xc = x \cdot x[0]$ (all known)

Clicker Question

How many phrases will LZW create on $S = a^n$, a run of n copies of a ?

A $\sim n$

B $\sim n/2$

C $\sim n/4$

D $\Theta(n/\log n)$

E $\Theta(\sqrt{n})$

F $\Theta(\log n)$

G $\Theta(\log \log n)$

H 2

I 1

→ sli.do/comp526

Clicker Question

a a a a a a a a a a a a a a a

k phrases

$$\sum_{i=1}^k i = \frac{k(k+1)}{2}$$
$$\sim k^2/2$$

How many phrases will LZW create on $S = a^n$, a run of n copies of a ?

A ~~n~~

B ~~$n/2$~~

C ~~$n/4$~~

D ~~$\Theta(n/\log n)$~~

E $\Theta(\sqrt{n})$ ✓

F ~~$\Theta(\log n)$~~

G ~~$\Theta(\log \log n)$~~

H ~~2~~

I ~~1~~

$$\frac{k^2}{2} \approx n$$

$$k = \Theta(\sqrt{n})$$

→ sli.do/comp526

LZW – Discussion

- ▶ As presented, LZW uses coded alphabet $\Sigma_C = [0..2^d)$.
 - ↪ use another encoding for code numbers \mapsto binary, e. g., Huffman
- ▶ need a rule when dictionary is full; different options:
 - ▶ increment d ↪ longer codewords
 - ▶ “flush” dictionary and start from scratch ↪ limits extra space usage
 - ▶ often: reserve a codeword to trigger flush at any time
- ▶ encoding and decoding both run in linear time (assuming $|\Sigma_S|$ constant)

LZW – Discussion

fast encoding & decoding

works in streaming model (no random access, no backtrack on input needed)

significant compression for many types of data

captures only local repetitions (with bounded dictionary)

Compression summary

Huffman codes	Run-length encoding	Lempel-Ziv-Welch
fixed-to-variable	variable-to-variable	variable-to-fixed
2-pass	1-pass	1-pass
must send dictionary	can be worse than ASCII	can be worse than ASCII
60% compression on English text	bad on text	45% compression on English text
optimal binary character encoding	good on long runs (e.g., pictures)	good on English text
rarely used directly	rarely used directly	frequently used
part of pkzip, JPEG, MP3	fax machines, old picture-formats	GIF, part of PDF, Unix compress

Part III

Text Transforms

Text transformations

- ▶ compression is effective if we have one the following:
 - ▶ long runs \rightsquigarrow RLE
 - ▶ frequently used characters \rightsquigarrow Huffman
 - ▶ many (locally) repeated substrings \rightsquigarrow LZW

Text transformations

- ▶ compression is effective if we have one the following:
 - ▶ long runs \rightsquigarrow RLE
 - ▶ frequently used characters \rightsquigarrow Huffman
 - ▶ many (locally) repeated substrings \rightsquigarrow LZW
- ▶ but methods can be frustratingly “blind” to other “obvious” redundancies
 - ▶ LZW: repetition too distant ⚡ dictionary already flushed
 - ▶ Huffman: changing probabilities (local clusters) ⚡ averaged out globally
 - ▶ RLE: run of alternating pairs of characters ⚡ not a run

Text transformations

- ▶ compression is effective if we have one the following:
 - ▶ long runs \rightsquigarrow RLE
 - ▶ frequently used characters \rightsquigarrow Huffman
 - ▶ many (locally) repeated substrings \rightsquigarrow LZW
- ▶ but methods can be frustratingly “blind” to other “obvious” redundancies
 - ▶ LZW: repetition too distant ⚡ dictionary already flushed
 - ▶ Huffman: changing probabilities (local clusters) ⚡ averaged out globally
 - ▶ RLE: run of alternating pairs of characters ⚡ not a run
- ▶ Enter: **text transformations**
 - ▶ invertible functions of text
 - ▶ do not by themselves reduce the space usage
 - ▶ but help compressors “see” existing redundancy
 - \rightsquigarrow use as pre-/postprocessing in compression pipeline

5.8 Move-to-Front Transformation

Move to Front

- ▶ *Move to Front (MTF)* is a heuristic for self-adjusting linked lists
 - ▶ unsorted linked list of objects
 - ▶ whenever an element is accessed, it is moved to the front of the list (leaving the relative order of other elements unchanged)
- ~> list “learns” probabilities of access to objects
makes access to frequently requested ones cheaper

Move to Front

- ▶ *Move to Front (MTF)* is a heuristic for *self-adjusting linked lists*
 - ▶ unsorted linked list of objects
 - ▶ whenever an element is accessed, it is moved to the front of the list (leaving the relative order of other elements unchanged)
 - ↪ list “learns” probabilities of access to objects
makes access to frequently requested ones cheaper
- ▶ Here: use such a list for storing source alphabet Σ_S
 - ▶ to encode c , access it in list
 - ▶ encode c using its (old) position in list
 - ▶ then apply MTF to the list
 - ↪ codewords are integers, i. e., $\Sigma_C = [0..\sigma)$

Move to Front

- ▶ *Move to Front (MTF)* is a heuristic for *self-adjusting linked lists*
 - ▶ unsorted linked list of objects

 - ▶ encode c using its (old) position in list
 - ▶ then apply MTF to the list
 - ↪ codewords are integers, i. e., $\Sigma_C = [0..\sigma)$
- ↪ clusters of few characters ↪ many small numbers

Clicker Question

Assume a MTF list currently contains the items $X Y Z A B C$, and we now access A . What is the list content after the MTF rule has been applied?

→ sli.do/comp526

MTF – Code

► Transform (encode):

```
1 procedure MTF–encode( $S[0..n]$ )
2    $L :=$  list containing  $\Sigma_S$  (sorted order)
3    $C := \varepsilon$ 
4   for  $i := 0, \dots, n - 1$  do
5      $c := S[i]$ 
6      $p :=$  position of  $c$  in  $L$ 
7      $C := C \cdot p$ 
8     Move  $c$  to front of  $L$ 
9   end for
10  return  $C$ 
```

► Inverse transform (decode):

```
1 procedure MTF–decode( $C[0..m]$ )
2    $L :=$  list containing  $\Sigma_S$  (sorted order)
3    $S := \varepsilon$ 
4   for  $j := 0, \dots, m - 1$  do
5      $p := C[j]$ 
6      $c :=$  character at position  $p$  in  $L$ 
7      $S := S \cdot c$ 
8     Move  $c$  to front of  $L$ 
9   end for
10  return  $S$ 
```

► Important: encoding and decoding produce same accesses to list

MTF – Example

 \end{array}$$

- What does a run in S encode to in C ? *0s after first letter of run*
- What does a run in C mean about the source S ?

MTF – Discussion

- ▶ MTF itself does not compress text (if we store codewords with fixed length)

~> used as part of longer pipeline

- ▶ Intuitively effect:

MTF converts locally low empirical entropy to globally low empirical entropy(!)

~> makes Huffman coding much more effective!

- ▶ cheaper option: Elias gamma code

~>

smaller numbers gets shorter codewords

works well for text with small “local effective” alphabet

 many natural texts do not have locally low empirical entropy

 but we can often make it so . . . stay tuned (→ BWT)
