

# 12 Dynamic Programming

26 January 2026

Prof. Dr. Sebastian Wild

# Learning Outcomes

## Unit 12: *Dynamic Programming*

1. Be able to apply the DP paradigm to solve new problems.

## Outline

# 12 Dynamic Programming

- 12.1 Elements of Dynamic Programming
- 12.2 DP & Matrix Chain Multiplication
- 12.3 Greedy as Special Case of DP
- 12.4 The Bellman-Ford Algorithm
- 12.5 Making Change in Pre-1971 UK
- 12.6 Optimal Merge Trees & Optimal BSTs
- 12.7 Edit Distance

## 12.1 Elements of Dynamic Programming

# Introduction

applicable to many problems

- ▶ **Dynamic Programming (DP)** is a powerful algorithm **design pattern** for exact solutions to **optimization** problems
- ▶ Some commonalities with Greedy Algorithms, but with an element of brute force added in

*DP = “careful brute force”* (Erik Demaine)

- ▶ often yields polynomial time, but usually not linear time algorithms
- ▶ for many problems the *only* way we know to build efficient algorithms
- ▶ **Naming fun:** The term “dynamic programming”, due to Richard Bellman from around 1953, does not refer to computer programming; rather to a program (= plan, schedule) changing with time. It seems to have been at least partly marketing babble devoid of technical meaning ...

# Plan of the Unit

1. Abstract steps of DP (briefly)
2. Details on a concrete example (*matrix chain multiplication*)
3. More examples!

# The 6 Steps of Dynamic Programming

1. Define **subproblems** (and relate to original problem)
  2. **Guess** (part of solution)  $\rightsquigarrow$  local brute force
  3. Set up **DP recurrence** (for quality of solution)
  4. Recursive implementation with **Memoization**
  5. Bottom-up **table filling** (topological sort of subproblem dependency graph)
  6. **Backtracing** to reconstruct optimal solution
- Steps 1–3 require insight / creativity / intuition;  
Steps 4–6 are mostly automatic / same each time
- $\rightsquigarrow$  Correctness proof usually at level of DP recurrence
-  running time too! worst case time = #subproblems · time to find single best guess

# When does DP (not) help?

- ▶ *No Silver Bullet*

DP is the most widely applicable design technique, but can't *always* be applied

1. Vitally important for DP to be correct:

*Bellman's Optimality Criterion*

*For a correctly guessed fixed part of the solution,  
any optimal solution to the corresponding subproblems  
must yield an optimal solution to the overall problem (once combined).*

2. Also, the total **number of different subproblems** should be “*small*”  
(DP potentially still works correctly otherwise, but won’t be *efficient*.)

at most polynomial in  $n$

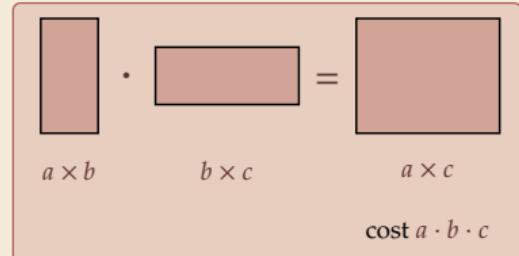

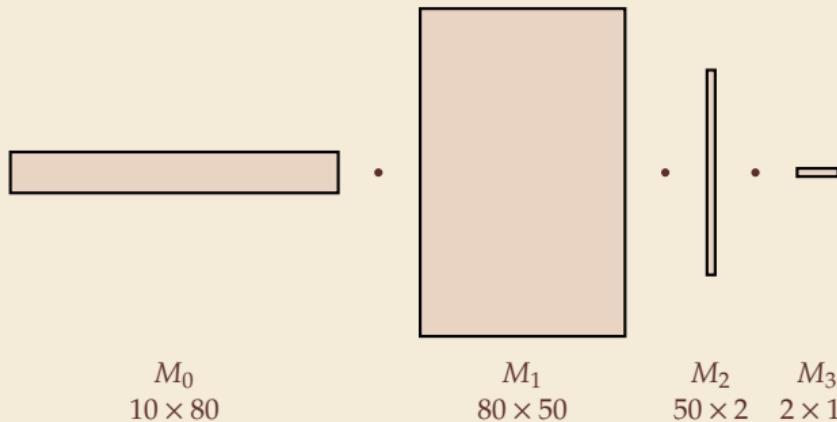

## 12.2 DP & Matrix Chain Multiplication

# The Matrix-Chain Multiplication Problem

Consider the following exemplary problem

- ▶ We have a product  $M_0 \cdot M_1 \cdot \dots \cdot M_{n-1}$  of  $n$  matrices to compute
- ▶ Since (matrix) multiplication is associative, it can be evaluated in different orders.
- ▶ For non-square matrices of different sizes, different order can change costs dramatically
  - ▶ Assume elementary matrix multiplication algorithm:
    - ~~> Multiplying  $a \times b$ -matrix with  $b \times c$  matrix costs  $a \cdot b \cdot c$  integer multiplications
- ▶ Given: Row and column counts  $r[0..n)$  and  $c[0..n)$  with  $r[i+1] = c[i]$  for  $i \in [0..n-1)$   
(corresponding to matrices  $M_0, \dots, M_{n-1}$  with  $M_i \in \mathbb{R}^{r[i] \times c[i]}$ )
- ▶ Goal: parenthesization of the product chain with minimal cost  
really a binary tree with  $n$  leaves!

# Matrix-Chain Multiplication – Example

Parenthesization	Cost (integer multiplications)
$M_0 \cdot (M_1 \cdot (M_2 \cdot M_3))$	$1000 + 40\,000 + 8000 = 49\,000$
$M_0 \cdot ((M_1 \cdot M_2) \cdot M_3)$	$8000 + 1600 + 8000 = 17\,600$
$(M_0 \cdot M_1) \cdot (M_2 \cdot M_3)$	$40\,000 + 1000 + 5000 = 46\,000$
$(M_0 \cdot (M_1 \cdot M_2)) \cdot M_3$	$8000 + 1600 + 200 = 9\,800$
$((M_0 \cdot M_1) \cdot M_2) \cdot M_3$	$40\,000 + 1000 + 200 = 41\,200$

first or last operation  
↓  
Greedy fails both ways!

# Matrix-Chain Multiplication – How about Brute Force?

If Greedy doesn't give optimal parenthesization, maybe just try all?

- ▶ parenthesizations for  $n$  matrices = binary trees with  $n$  leaves (*evalution trees*)  
= binary trees with  $n - 1$  (internal) nodes
- ▶ How many such trees are there?

- ▶ Let's write  $m = n - 1$ ;
- ▶  $C_0 = 1, C_1 = 1, C_2 = 2, C_3 = 5$

- ▶  $C_m = \sum_{r=1}^m C_{r-1} \cdot C_{m-r} \quad (m \geq 1)$

generating functions / combinatorics / guess (OEIS!) & check ...

- ▶  $\checkmark$  Can show  $C_n = \frac{1}{n+1} \binom{2n}{n} \sim \frac{1}{\sqrt{\pi}} \cdot \frac{4^n}{n^{3/2}}$

~~ exponentially many trees (almost  $4^n$ )

$$C_{20} = 6\,564\,120\,420, \quad C_{30} = 3\,814\,986\,502\,092\,304$$

- ~~ A brute-force approach is utterly hopeless
- ~~ Dynamic programming to the rescue!

# Matrix-Chain Multiplication – Step 1: Subproblems

- ▶ Key ingredient for DP: Problem allows for recursive formulation  
Need to decide:
  1. What are the **subproblems** to consider?
  2. How can the **original problem** be expressed as subproblem(s)?
- ▶ Often requires to solve a more general version of the problem

- |  |
|--|
| <ol style="list-style-type: none"><li>1. Subproblems</li><li>2. Guess!</li><li>3. DP Recurrence</li><li>4. Memoization</li><li>5. Table Filling</li><li>6. Backtrace</li></ol> |
|--|

Here:

1. **Subproblems** = Ranges of matrices  $[i..j)$   $0 \leq i \leq j \leq n$   
i. e., optimal parenthesization for each range  $M_i, M_{i+1}, \dots, M_{j-1}$
2. **Original problem** = range  $[0..n)$

## ▶ Intuition:

- ▶ Any subtree in binary multiplication tree covers some range  $[i..j)$   
(matrix multiplication is not commutative  $\rightsquigarrow$  left-right order has to stay)
- ▶ left and right factors of a multiplication don't "see/influence" each other

# Matrix-Chain Multiplication – Step 2: Guess

- ▶ Usually, any subproblem can be split into smaller subproblems in **several** ways
- ▶ Which way to decompose gives best solution not known *a priori*
  - ~~> What do we have to correctly *guess* to solve the problem?
- ▶ Here: **Guess** last multiplication / root of binary tree
  - ~~> index  $k \in [i + 1..j]$  so that  $[i..j]$  computed with **last** multiplication
$$(M_i \cdot \dots \cdot M_{k-1}) \cdot (M_k \cdot \dots \cdot M_{j-1})$$
  - ~~> optimal parenthesization of  $M_i, \dots, M_{k-1}$  and  $M_k, \dots, M_{j-1}$  computed recursively  
(corresponds to subproblems  $[i..k]$  and  $[k..j]$ )

1. Subproblems
2. Guess!
3. DP Recurrence
4. Memoization
5. Table Filling
6. Backtrace

# Matrix-Chain Multiplication – Step 3: DP Recurrence

- With subproblems and guessed part fixed,  
we try to express total **value/cost of solution** *recursively*

~ We ignore the actual solution and just compute its cost!

- Often good to prove correctness at level of recurrence

- Subproblems
- Guess!
- DP Recurrence
- Memoization
- Table Filling
- Backtrace

- Here: **Recurrence** for  $m(i, j)$  = total number of integer multiplications  
used in best parenthesization of  $[i..j)$

~ Set up recurrence, including any base cases.

$$m(i, j) = \begin{cases} 0 & \text{if } j - i \leq 1 \\ \min \left\{ \begin{array}{c} \text{recursive cost} \\ \boxed{m(i, k) + m(k, j) + r[i] \cdot r[k] \cdot c[j-1]} \\ : k \in [i+1..j] \end{array} \right\} & \text{otherwise} \end{cases}$$

best  $k$  chosen by *local brute force*

recursive cost

cost of last multiplication

# Matrix-Chain Multiplication – Correctness

**Claim:** Let  $m(i, j)$  for  $0 \leq i \leq j \leq n$  be defined by the recurrence

$$m(i, j) = \begin{cases} 0 & \text{if } j - i \leq 1 \\ \min\{m(i, k) + m(k, j) + r[i] \cdot r[k] \cdot c[j - 1] : k \in [i + 1..j]\} & \text{otherwise} \end{cases}$$

Then  $m(i, j) = \#$ integer multiplications in best parenthesization of  $M_i \cdots M_{j-1}$ .

*Proof:* By induction over  $j - i$

- ▶ **IB:** When  $j - i \leq 1$  we have an empty product ( $j = i$ ) or a single matrix ( $j = i + 1$ )  
In both cases, no multiplications are needed and  $m(i, j) = 0$ .
- ▶ **IS:** Given  $j - i \geq 2$  matrices and an optimal evalution tree  $T$  for them.
  - ▶  $T$ 's root must be a last product of left and right subterms  $(M_i \cdots M_{k-1}) \cdot (M_k \cdots M_{j-1})$  for some  $i < k < j$ , with cost  $r[i]r[k]c[j - 1]$ .
  - ▶ Moreover, left and right subtree  $T_\ell$  and  $T_r$  of the root must be optimal evaluation trees for subproblems  $[i..k)$  and  $[k..j)$ ; (otherwise can improve  $T$ )
    - ~~> By IH, the cost of  $T_\ell$  and  $T_r$  are given by  $m(i, k)$  and  $m(k, j)$
    - ~~>  $m(i, j) = \text{cost of } T$

# Matrix-Chain Multiplication – Step 4: Memoization

- ▶ Write **recursive** function to compute recurrence
- ▶ But *memoize* all results! (symbol table: subproblem  $\mapsto$  optimal cost )
- ~~ First action of function: check if subproblem known
  - ▶ If so, return cached optimal cost
  - ▶ Otherwise, compute optimal cost and remember it!

1. Subproblems
2. Guess!
3. DP Recurrence
4. Memoization
5. Table Filling
6. Backtrace

---

```
1 procedure totalMults( $r[i..j], c[i..j]$ ):  
2   if  $j - i \leq 1$   
3     return 0  
4   else  
5     best :=  $+\infty$   
6     for  $k := i + 1, \dots, j - 1$   
7        $m_l :=$  cachedTotalMults( $r[i..k], c[i..k]$ )  
8        $m_r :=$  cachedTotalMults( $r[k..j], c[k..j]$ )  
9        $m := m_l + m_r + r[i] \cdot r[k] \cdot c[j - 1]$   
10      best := min{best, m}  
11    end for  
12    return best
```

---

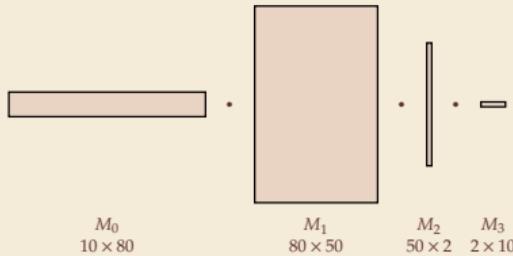

$$m(i, j) = \begin{cases} 0 & \text{if } j - i \leq 1 \\ \min\{m(i, k) + m(k, j) + r[i] \cdot r[k] \cdot c[j - 1] : k \in [i + 1 .. j]\} & \text{otherwise} \end{cases}$$

---

```
13 procedure cachedTotalMults( $r[i..j], c[i..j]$ ):  
14   //  $m[0..n][0..n]$  initialized to NULL at start  
15   if  $m[i][j] == \text{NULL}$   
16      $m[i][j] :=$  totalMults( $r[i..j], c[i..j]$ )  
17   return  $m[i][j]$ 
```

---

# Matrix-Chain Multiplication – Example Memoization

$$n = 4$$

$$r[0..n) = [10, 80, 50, 2]$$

$$c[0..n) = [80, 50, 2, 10]$$

$i \backslash j$	0	1	2	3	4
$m[i][j]$	0	0	40000	9600	9800
0	—	0	0	8000	9600
1	—	—	0	0	1000
2	—	—	—	0	0
3	—	—	—	—	0
4	—	—	—	—	0

# Matrix-Chain Multiplication – Runtime Analyses

---

```
1 procedure totalMults( $r[i..j], c[i..j]$ ):
2     if  $j - i \leq 1$ 
3         return 0
4     else
5         best :=  $+\infty$ 
6         for  $k := i + 1, \dots, j - 1$ 
7              $m_l := \text{cachedTotalMults}(r[i..k], c[i..k])$ 
8              $m_r := \text{cachedTotalMults}(r[k..j], c[k..j])$ 
9              $m := m_l + m_r + r[i] \cdot r[k] \cdot c[j - 1]$ 
10            best := min{best, m}
11        end for
12        return best
```

---

↝ total running time  $O(n^3)$

---

```
13 procedure cachedTotalMults( $r[i..j], c[i..j]$ ):
14     //  $m[0..n][0..n]$  initialized to NULL at start
15     if  $m[i][j] == \text{NULL}$ 
16          $m[i][j] := \text{totalMults}(r[i..j], c[i..j])$ 
17     return  $m[i][j]$ 
```

---

- ▶ With memoization, compute each subproblem at most once
- ▶ nonrecursive cost (totalMults):  
 $O(j - i) = O(n)$
- ▶ Number of subproblems  $[i..j]$  for  $0 \leq i \leq j \leq n$

$$\sum_{0 \leq i \leq j \leq n} 1 = \sum_{i=0}^n \sum_{j=i}^n 1 = \Theta(n^2)$$

# Matrix-Chain Multiplication – Step 5: Table Filling

- ▶ Recurrence induces a DAG on subproblems (who calls whom)
  - ▶ Memoized recurrence traverses this DAG (DFS!)
  - ▶ We can slightly improve performance by systematically computing subproblems following a fixed topological order
- ▶ Topological order here: by **increasing length**  $\ell = j - i$ , then by  $i$

1. Subproblems
2. Guess!
3. DP Recurrence
4. Memoization
5. Table Filling
6. Backtrace

---

```
1 procedure totalMultsBottomUp( $r[0..n]$ ,  $c[0..n]$ ):  
2    $m[0..n][0..n] := 0$  // initialize to 0  
3   for  $\ell = 2, 3, \dots, n$  // iterate over subproblems ...  
4     for  $i = 0, 1, \dots, n - \ell$  // ... in topological order  
5        $j := i + \ell$   
6        $m[i][j] := +\infty$   
7       for  $k := i + 1, \dots, j - 1$   
8          $q := m[i][k] + m[k][j] + r[i] \cdot r[k] \cdot c[j - 1]$   
9          $m[i][j] := \min\{m[i][j], q\}$   
10    return  $m[0..n][0..n]$ 
```

---

- ▶ Same  $\Theta$ -class as memoized recursive function
- ▶ In practice usually substantially faster
  - ▶ lower overhead
  - ▶ predictable memory accesses

# Matrix-Chain Multiplication – Step 6: Backtracing

- ▶ So far, only determine the **cost** of an optimal solution
  - ▶ But we also want the solution itself
- ▶ By *retracing* our steps, we can determine/construct one!
- ▶ Here: output a parenthesized term recursively

---

```
1 procedure matrixChainMult(r[0..n), c[0..n]):
2     m[0..n][0..n) := totalMultsBottomUp(r[0..n), c[0..n])
3     return traceback([0..n])
4
5 procedure traceback([i..j]):
6     if j - i == 1
7         return Mi
8     else
9         for k := i + 1, ..., j - 1
10            q := m[i][k] + m[k][j] + r[i] · r[k] · c[j - 1]
11            if m[i][j] == q
12                return (traceback([i..k])) · (traceback([k..j]))
13            end for
14        end if
```

---

- 1. Subproblems
- 2. Guess!
- 3. DP Recurrence
- 4. Memoization
- 5. Table Filling
- 6. Backtrace

- ▶ follow recurrence a second time
- ▶ always have for running time:  
backtracing =  $O(\text{computing } M)$
- ↝ computing optimal cost and  
computing optimal solution have  
same complexity
- ▶ speedup possible by  
remembering correct guess *k* for  
each subproblem

# Summary: The 6 Steps of Dynamic Programming

1. Define **subproblems** and how **original problem** is solved
2. What part of solution to **guess**?
3. Set up **DP recurrence** for quality/cost of solution

~~ Prove **correctness** here: induction over subproblems following recurrence  
~~ Analyze running **time complexity** here: #subproblems · non-recursive time

—(Basically) cookie-cutter approach from here on —

4. Recursive implementation with **Memoization**: mutually recursive functions with cache  
*or*
5. Bottom-up **table filling**: define topological order of subproblem dependency graph
6. **Backtracing** to reconstruct optimal solution: Recursively retrace cost recurrence

1. Subproblems
2. Guess!
3. DP Recurrence
4. Memoization
5. Table Filling
6. Backtrace

## 12.3 Greedy as Special Case of DP

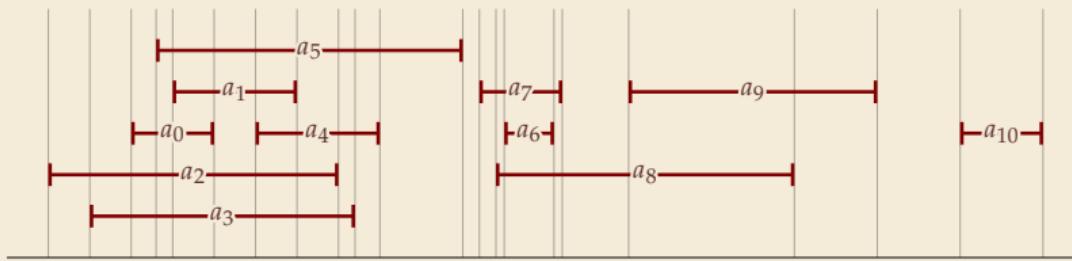

# Dynamic Greedy

- ▶ Every Greedy Algorithm can also be seen as a DP algorithm **without guessing**
  - ~~ For new problems, it can help to first follow the DP roadmap and then check if we can select the “correct” guess without local brute force
- ▶ If so, we then recurse on a single branch of subproblems
  - ~~ Greedy Algorithm doesn’t need memoization or bottom-up table filling, but can do direct recursion instead

# Recall Unit 11

## The Activity selection problem

- ▶ **Activity Selection:** scheduling for *single* machine, jobs with *fixed* start and end times  
pick a *subset* of jobs without *conflicts*  
Formally:
  - ▶ **Given:** Activities  $A = \{a_0, \dots, a_{n-1}\}$ , each with a start time  $s_i$  and finish time  $f_i$   
 $(0 \leq s_i < f_i < \infty)$
  - ▶ **Goal:** Subset  $I \subseteq [0..n]$  of tasks such that  $i, j \in I \wedge i \neq j \implies [s_i, f_i) \cap [s_j, f_j) = \emptyset$   
and  $|I|$  is maximal among all such subsets
  - ▶ We further assume that jobs are sorted by finish time, i.e.,  $f_0 \leq f_1 \leq \dots \leq f_{n-1}$   
(if not, easy to sort them in  $O(n \log n)$  time)

# DP Algorithm for Activity Selection

**1. Subproblems:**  $A_{i,j} = \{a_\ell \in A : s_\ell \geq f_i \wedge f_\ell \leq s_j\}$

(after  $a_i$  finishes and before  $a_j$  begins)

**Original problem:**  $A_{-1,n}$  with dummy tasks  $f_{-1} = -\infty, s_n = +\infty$

- 1. Subproblems
- 2. Guess!
- 3. DP Recurrence
- 4. Memoization
- 5. Table Filling
- 6. Backtrace

**2. Guess:** Task  $k \in I^*$

**3. DP Recurrence:** Denote  $c(i, j) = |I^*(A_{i,j})|$  = maximum #independent tasks in  $A_{i,j}$

$$\rightsquigarrow c(i, j) = \begin{cases} 0, & \text{if } A_{i,j} = \emptyset; \\ \max\{c(i, k) + c(k, j) + 1 : a_k \in A_{i,j}\} & \text{otherwise.} \end{cases}$$

**4.–6.** *Omitted* (could be done following the standard scheme)

► Problem-specific insight from Unit 11  $\rightsquigarrow$  Can always use  $k = \min\{k : a_k \in A_{ij}\}$

(earliest finish time)

No guess needed!

## 12.4 The Bellman-Ford Algorithm

# Recall Shortest Paths

## ► Single Source Shortest Path Problem (SSSPP)

- Given: directed, edge-weighted, simple graph  $G = (V, E, c)$  with edge costs  $c : E \rightarrow \mathbb{R}$ , a start vertex  $s \in V$
- Goal: a data structure that reports for every  $v \in V$ :
  - $\delta_G(s, v)$ : the shortest-path distance from  $s$  to  $v$
  - $\text{spath}(v)$ : a shortest path from  $s$  to  $v$  (if it exists)
- $\delta_G(s, v) = \inf (\{\infty\} \cup \{c(w) : w \text{ an } s-v\text{-walk in } G\})$ 
  - Write  $\delta$  instead of  $\delta_G$  when graph clear from context
- Here: Assume **negative-weight edges** are present (otherwise Dijkstra suffices)
  - but for now: assume there is **no negative cycle**  
 $\rightsquigarrow \delta(s, v) > -\infty$  and can restrict to shortest **paths** (not walks)

# Shortest Paths as DP – Last Edge Decomposition

- Idea: Every nontrivial shortest path has a **last edge**. *We don't know which; so guess!*

~~ Subproblems: for  $w \in V$ , compute  $\delta(s, w)$ .

~~ Recurrence:  $\delta(s, w) = \min\{\delta(s, v) + c(vw) : vw \in E\}$

subproblem dependency graph is isomorphic to  $G^T$ ! ~~ doesn't work in general

~~ Yields usable (terminating!) algorithm iff  $G$  is a DAG.

To break the cycles, let's turn them into a helix!

- Need to build “layers” in the subproblem dependency graph, so that edges can't go back up.
- **Subproblems:**  $(w, \ell)$  for  $w \in V, \ell \in [0..n]$ , compute  $\delta_{\leq \ell}(s, w)$  where  $\delta_{\leq \ell}(s, v) = \min(\{+\infty\} \cup \{c(w) : w \text{ an } s-v\text{-walk with } \leq \ell \text{ edges}\})$
- **Original problems:**  $\ell = n - 1$  (without negative cycles, paths suffice)

► **Recurrence:**  $\delta_{\leq \ell}(s, w) = \begin{cases} \infty & \text{if } \ell = 0 \text{ and } s \neq w \\ 0 & \text{if } \ell = 0 \text{ and } s = w \\ \min\{\delta_{\leq \ell-1}(s, v) + c(vw) : vw \in E\} & \text{otherwise} \end{cases}$

## Shortest Paths as DP – Length Layers

# Hold On – What about negative cycles?

- The recurrence for  $\delta_{\leq \ell}$  seems to work fine with *negative* edges  
But  $G$  could contain a **negative-weight cycle**  $C$  ...

$$\delta_{\leq \ell}(s, w) = \begin{cases} \infty & \text{if } \ell = 0 \text{ and } s \neq w \\ 0 & \text{if } \ell = 0 \text{ and } s = w \\ \min\{\delta_{\leq \ell-1}(s, v) + c(vw) : vw \in E\} & \text{otherwise} \end{cases}$$

*Isn't that a contradiction to the non-existence of shortest walks?*

- No. If we restrict the length, shortest walks always exist.
- But: If there is a negative cycle  $C[0..k]$  with paths  $s \rightsquigarrow C$  and  $C \rightsquigarrow w$ ,  
then  $\delta_{\leq \ell}(s, w) > \delta_{\leq \ell+k}(s, w) > \delta_{\leq \ell+2k}(s, w) > \dots$  (and  $\delta(s, w) = -\infty$ )
- ~~ We can *detect* if any negative cycle is reachable from  $s$  by including more layers  $\ell \geq n$  and check if some vertex still improves.
  - *How many further layers do we need / when is it safe to stop?*

# Detecting negative cycles

We can detect reachable negative cycles by including just the *single* extra layer  $\ell = n$ !

**Lemma:**  $\exists w : \delta_{\leq n}(s, w) < \delta_{\leq n-1}(s, w)$  iff negative cycle reachable from  $s$

Proof:

- “ $\Rightarrow$ ”
- ▶ If some vertex  $w$  improves further, i.e.,  $\delta_{\leq n}(s, w) < \delta_{\leq n-1}(s, w)$   
a walk  $W[0..n]$  with  $c(W) = \delta_{\leq n}(s, w)$  was the **shortest** way to reach  $w$
  - $\rightsquigarrow W$  is a non-simple walk, i.e., it contains a cycle
  - ▶ Let  $P[0..k]$  be the path resulting from  $W$  by shortcutting all cycles  $\rightsquigarrow k \leq n - 1$
  - $\rightsquigarrow c(P) \geq \delta_{\leq n-1}(s, w) > \delta_{\leq n}(s, w) = c(W)$
  - $\rightsquigarrow \exists$  negative cycle reachable from  $s$

- “ $\Leftarrow$ ”
- ▶ Conversely, let negative cycle  $C[0..k]$  be reachable from  $s$
  - $\rightsquigarrow c(C) = \sum_{i=0}^{k-1} c(C[i]C[i+1]) < 0$
  - ▶ Assume towards a contradiction that  $\forall w : \delta_{\leq n}(s, w) = \delta_{\leq n-1}(s, w)$
  - $\rightsquigarrow \forall vw \in E : \delta_{\leq n-1}(s, w) \leq \delta_{\leq n-1}(s, v) + c(vw)$  (no update in layer  $\ell = n$ )
  - ▶ summing this inequality over  $C[0..k]$  yields (abbreviating  $\delta(w) := \delta_{\leq n-1}(s, w)$ )
$$\sum_{i=1}^k \delta(C[i]) \leq \sum_{i=1}^k (\delta(C[i-1]) + c(C[i]C[i+1])) = \sum_{i=0}^{k-1} \delta(C[i]) + \underbrace{\sum_{i=1}^k c(C[i]C[i+1])}_{=c(C)<0}$$
  - $\rightsquigarrow 0 \leq c(C) < 0$  

# Shortest Paths as DP – Template Algorithm

- ▶ Strictly following the template works ...
  - ▶ Subproblem order: by increasing  $\ell \in [0..n]$  and  $v \in V$
  - ▶ Bottom-up table filling:

---

```
1 procedure shortestPathsDP( $G, s$ ):  
2     // Base case  $\ell = 0$ :  
3      $\delta[0..n][0..n] := +\infty$  //  $\delta[\ell][v]$  will store  $\delta_{\leq \ell}(s, v)$   
4      $\delta[0][s] := 0$   
5     for  $\ell := 1, \dots, n$  // layer  
6         for  $w := 0, \dots, n - 1$  // vertex  
7             for  $vw \in E$   
8                  $\delta[\ell][w] := \min\{\delta[\ell][w], \delta[\ell - 1][v] + c(vw)\}$   
9     return  $\delta$ 
```

---

- 1. Subproblems
- 2. Guess!
- 3. DP Recurrence
- 4. Memoization
- 5. Table Filling
- 6. Backtrace

$$\delta_{\leq \ell}(s, w) = \begin{cases} \infty & \text{if } \ell = 0 \text{ and } s \neq w \\ 0 & \text{if } \ell = 0 \text{ and } s = w \\ \min\{\delta_{\leq \ell-1}(s, v) + c(vw) : vw \in E\} & \text{otherwise} \end{cases}$$

- ▶ ... but some improvements are possible!
  - ▶ Iterating over *incoming* edges is not convenient
    - ~~ order of updates within layer  $\ell$  doesn't matter ~~ iterate forwards!
  - ▶ only use final distances in the end; we waste space by keeping 2D array around
    - ~~ can actually just do updates in place, using a single array  $\delta$
    - ~~ Don't strictly solve subproblems  $(\ell, v)$  any more! (but final result correct)

# The Bellman-Ford Algorithm

```
1 procedure bellmanFord( $G, s$ ):  
2      $dist[0..n] := +\infty$ ;  $pred[0..n] := \text{null}$   
3      $dist[s] := 0$   
4     for  $\ell := 1, \dots, n - 1$   
5         for  $v := 0, \dots, n - 1$   
6             for  $(w, c) \in G.\text{adj}[v]$   
7                 if  $dist[w] > dist[v] + c$   
8                      $dist[w] := dist[v] + c$   
9                      $pred[w] := v$  // remember for backtrace  
10        for  $v := 0, \dots, n - 1$   
11            for  $(w, c) \in G.\text{adj}[v]$   
12                if  $dist[w] > dist[v] + c$   
13                    return HAS_NEGATIVE_CYCLE  
14    return  $(dist, pred)$ 
```

- ▶ Final algorithm  
(including shortest path tree via  $pred$ )
- ▶ Correctness:
  - ▶ by induction over loop iterations,  
show:
    - (a)  $dist[w] \leq \delta_{\leq \ell}(s, w)$  and if finite,
    - (b)  $dist[w]$  is  $c(P)$  for some  $s-w$ -path
  - ▶ negative cycle detection from Lemma
- ▶ Space:  $\Theta(n)$
- ▶ Running time:  $O(n(n + m))$

## Extensions:

- ▶ Can be implemented in  $O(nm)$  time by removing unreachable vertices from consideration
- ▶ Instead of only detecting a negative cycle, we can return one;  
we can also explicitly find all vertices with  $\delta(s, w) = -\infty$  (needs another traversal).
- ▶ Can terminate with smaller  $\ell$  if no distance changed  $\rightsquigarrow$  faster for some graphs

## 12.5 Making Change in Pre-1971 UK

# Recall Unit 11

## Greed For Change

The Change-Making Problem (a.k.a. Coin-Exchange Problem)

- ▶ Given: a set of integer denominations of coins  $w_1 < w_2 < \dots < w_k$  with  $w_1 = 1$ , target value  $n \in \mathbb{N}_{\geq 1}$  (we have sufficient supply of all coins ...)
- ▶ Goal: “fewest coins to give change  $n$ ”, i.e., multiplicities  $c_1, \dots, c_k \in \mathbb{N}_{\geq 0}$  with  $\sum_{i=1}^k c_i \cdot w_i = n$  minimizing  $\sum_{i=1}^k c_i$

For Euro coins, denominations are  $(1\text{€}), (2\text{€}), (5\text{€}), (10\text{€}), (20\text{€}), (50\text{€}), (1\text{€}),$  and  $(2\text{€})$ .

formally:  $1, 2, 5, 10, 20, 50, 100,$  and  $200.$   
 $w_1 \quad w_2 \quad w_3 \quad w_4 \quad w_5 \quad w_6 \quad w_7 \quad w_8$

~~ Simple greedy algorithm:  
largest coins first

- ▶ optimal time ( $O(k)$ ) if coins sorted)
- ▶ is  $\sum c_i$  minimal?

---

```
1 procedure greedyChange(w[1..k], n):
2     // Assumes 1 = w[1] < w[2] < ... < w[k]
3     for i := k, k - 1, ..., 1:
4         c[i] := ⌊n / w[i]⌋
5         n := n - c[i] · w[i]
6     // Now n == 0
7     return c[1..k]
```

---

# Pre-Decimal English Coins

We discussed that for some (unwise) choices of denominations, Greedy cannot give optimal change.  
Welcome to Britain until 1971!

## British Pre-Decimal Coins:

- ▶  $\frac{1}{2}$  penny,
  - ▶ 1 penny,
  - ▶ 3 pence,
  - ▶ 6 pence,
  - ▶ shilling = 12 pence,
  - ▶ florin = 24 pence
  - ▶ half-crown = 30 pence
  - ▶ crown = 60 pence
  - ▶ pound = 240 pence
  - ▶ guinea =  $21 \cdot 12 = 252$  pence  
(obsolete as coin since 1816)
- ~~> Greedy would give 48 pence as 30p + 12p + 6p
- ▶ obviously, 2 florins are more efficient
- ~~> How to solve exactly?
- As the old saying goes ...
- Where Greedy fails, DP prevails.  
(but mind details, and how it scales)

# Making Change by DP

Idea: Every solution must pick a first coin. Which one? Unclear, so guess!

- **Subproblems:** Change for  $m \in [0..n]$  (with coins  $w_1, \dots, w_k$ )  
Original problem  $m = n$

- **Guess:** first coin  $w_i$  to use

- **Recurrence**  $C(m) = \text{smallest } \# \text{coins to give change } m$

$$C(m) = \begin{cases} 0 & \text{if } m = 0 \\ 1 + \min\{C(m - w_i) : i \in [1..k] \wedge w_i \leq m\} & \text{otherwise} \end{cases}$$

- **Bottom-up implementation & Backtrace**

---

```
1 procedure dpChange(w[1..k], n):
2     C[0..n] := +∞
3     C[0] := 0
4     for m := 1, …, n
5         for i := 1, …, k
6             if w[i] ≥ m
7                 q := 1 + C[m - w[i]]
8                 C[m] := min{C[m], q}
9     return C[n]
```

---

---

```
1 procedure tracebackChange(w[1..k], n):
2     C[0..n] := dpChange(w[1..k], n)
3     c[1..k] := 0 // coin multiplicities
4     m := n
5     while m > 0
6         for i := 1, …, k
7             if w[i] ≥ m ∧ C[m] == 1 + C[m - w[i]]
8                 c[i] := c[i] + 1; m := m - w[i]
9     return c[1..k]
```

# Making Change by DP – Analysis

- ▶ **Input:** denominations of coins

$w_1 < w_2 < \dots < w_k$  with  $w_1 = 1$ ,  
target value  $n \in \mathbb{N}_{\geq 1}$

- ▶ **Space:**  $\Theta(n)$

#subproblems  
time per subproblem

- ▶ **Running Time:**  $O(n \cdot k)$

*How good is this running time?*

- ▶ A linear function in both input numbers seems decent, right? (If  $k$  and  $n$  small, certainly Yes.)
  - ▶ Running time is also certainly a *polynomial* in  $n$  and  $k$
- ▶ But: In terms of *computational complexity*, dpChange is an **exponential-time algorithm!**
  - ▶ Reason: We give the input **number**  $n$  in **binary**, so  $n$  is exponential in its *input size*.
- ⚠ Must distinguish: *value* of a number (in the input) vs. *size* of the (encoding of the) input
  - ~~> dpChange is a *pseudo-polynomial time* algorithm
- ▶ Actually, the general making-change problem is NP-complete (!)

---

```
1 procedure dpChange(w[1..k], n):
2     C[0..n] := +∞
3     C[0] := 0
4     for m := 1, …, n
5         for i := 1, …, k
6             if w[i] ≥ m
7                 q := 1 + C[m - w[i]]
8                 C[m] := min{C[m], q}
9     return C[n]
```

---

# Knapsack

Let's look at slightly more interesting problem: *Knapsack* („Rucksack“).

## The 0/1-Knapsack Problem

a.k.a. the burglar's problem

- ▶ Given:  $k$  items with weights  $w_1, \dots, w_k \in \mathbb{N}_{\geq 1}$  and values  $v_1, \dots, v_k \in \mathbb{R}_{\geq 0}$ ; a weight budget  $W \in \mathbb{N}$
- ▶ Goal: Subset  $I \subseteq [1..k]$  such that  $\sum_{i \in I} w_i \leq W$  with maximum  $\sum_{i \in I} v_i$ .  
Variant closer to Making change: Can use each item several times

- ▶ Recall from tutorials: Greedy fails miserably in general.

~~ Let's try DP!

- ▶ Subproblems:  $B \in [0..W]$ , best value with total weight  $\leq B$

- ▶ Guess: first item  $i$  with  $w_i \leq B$ .

⚡ Subproblem not of same type since  $w_i$  no longer there!

~~  $2^k$  possible “states” to be in (items already used) (0/1-Knapsack)

⚡ need a table of size  $W \cdot 2^k \dots$  might as well do brute force then!

- |                  |
|------------------|
| 1. Subproblems   |
| 2. Guess!        |
| 3. DP Recurrence |
| 4. Memoization   |
| 5. Table Filling |
| 6. Backtrace     |

# Knapsack by DP

~ Force order to consider items in!

► Let's refine the guessing part to

**Guess:** Whether or not to include the *last* item ( $k$ )

~ For subproblem, restrict to items  $1, \dots, k - 1$  (in either case)

~ **Subproblems:**  $(\ell, B)$  for  $\ell \in [1..k]$  and  $B \in [0..W]$

$$V(\ell, B) = \max_I \sum_{i \in I} v_i \text{ over sets of items } I \subset [1..\ell] \text{ with } \sum_{i \in I} w_i \leq B$$

Original problem corresponds to  $V(k, W)$

► **Recurrence:**  $V(\ell, B) = \begin{cases} 0 & \text{if } \ell = 1 \wedge w_1 > B \\ v_1 & \text{if } \ell = 1 \wedge w_1 \leq B \\ \max\{v_\ell + V(\ell - 1, B - w_k), V(\ell - 1, B)\} & \text{otherwise} \end{cases}$

**Cookie-Cutter Steps 4.–6. Omitted**

►  $V(\ell, \cdot)$  only needs  $V(\ell - 1, \cdot)$  ~ two arrays  $V[0..W]$  and  $V_{\text{prev}}[0..W]$  suffice  
~  $\Theta(W)$  space,  $\Theta(W \cdot k)$  time (pseudo-polynomial algorithm)

1. Subproblems

3. DP Recurrence
4. Memoization
5. Table Filling
6. Backtrace

## 12.6 Optimal Merge Trees & Optimal BSTs

# Recall Unit 4

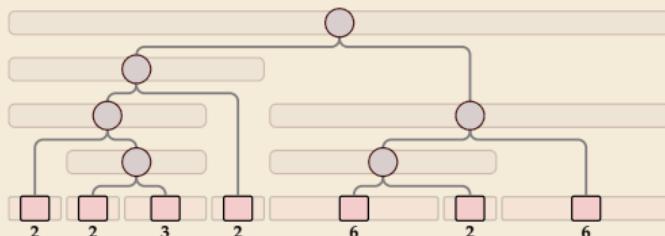

## Good merge orders

Let's take a step back and breathe.

- ▶ Conceptually, there are two tasks:

1. Detect and use existing runs in the input  $\rightsquigarrow \ell_1, \dots, \ell_r$  (easy) ✓
2. Determine a favorable **order of merges** of runs ("automatic" in top-down mergesort)

$$\begin{aligned}\text{Merge cost} &= \text{total area of } \boxed{\text{rectangle}} \\ &= \text{total length of paths to all array entries} \\ &= \sum_{w \text{ leaf}} \text{weight}(w) \cdot \text{depth}(w)\end{aligned}$$

well-understood problem  
with known algorithms

$\rightsquigarrow$  **optimal merge tree**  
= optimal **binary search tree**  
for leaf weights  $\ell_1, \dots, \ell_r$   
(optimal expected search cost)

# Optimal Alphabetic Trees

"well-understood problem with known algorithms" . . . let's make it so 😊

- ▶ **Given:** Leaf weights  $\ell_0, \dots, \ell_n$       normalized to  $\ell_0 + \dots + \ell_n = 1$
- ▶ **Goal:** Binary search tree  $T$  with  $n + 1$  null pointers  $L_0, \dots, L_n$ , such that

$$c(T) := \sum_{i=1}^n \ell_i \cdot \text{depth}_T(L_i) \text{ is minimized}$$

- ▶ **Equivalent interpretations:**

1. *Optimal Static BST* with keys  $1, 2, \dots, n$   
     $\rightsquigarrow$  leaf  $L_i$  reached when searching for  $i + 0.5$     $\rightsquigarrow$   $c(T)$  expected cost of unsuccessful search  
    #comparisons  
    ↓
2. *Alphabetic code* for  $\sigma = n + 1$  symbols; like Huffman code, but codewords must retain order  
(if  $i < j$  then the codeword for  $i$  lexicographically smaller than codeword for  $j$ )  
     $\rightsquigarrow$   $c(T)$  expected codeword length
  - ▶ Inherit lower bound from Huffman codes:  $c(T) \geq \mathcal{H}$  with  $\mathcal{H} = \sum_{i=0}^n \ell_i \cdot \log_2\left(\frac{1}{\ell_i}\right)$
3. *Merge tree* for adaptive sorting;  $c(T) = \text{merge cost per element}$ .
  - ▶ Via Peeksor or Powersort know methods to achieve  $c(T) \leq \mathcal{H} + 2$
  - ▶ But neither are in general optimal

# Optimal Alphabetic Trees by DP

► **Guess:** (Key in) root  $r \in [1..n]$  of BST  $T$  (= #leaves in left subtree)

► **Subproblems:**  $[i..j]$  for  $0 \leq i < j \leq n + 1$

$C(i, j)$  = cost of opt. BST with leaf weights  $\ell_i, \dots, \ell_{j-1}$

Original problem:  $C(0, n + 1)$

1. Subproblems
2. Guess!
3. DP Recurrence
4. Memoization
5. Table Filling
6. Backtrace

► **Recurrence:**

$$C(i, j) = \begin{cases} 0 & \text{all leaves in subtree pay 1 at root...} \\ \ell_i + \dots + \ell_{j-1} + \min\{C(i, r) + C(r, j) : r \in [i+1..j-1]\} & \text{if } j - i = 1 \\ & \quad \uparrow \\ & \quad \dots \text{ plus cost to continue in left/right subtree} \end{cases} \quad \text{otherwise}$$

~~~ Obtain a  $O(n^3)$  time and  $O(n^2)$  space algorithm

# Optimal Binary Search Trees

- ▶ Algorithm can be generalized to Optimal BSTs when also internal nodes have weights
  - ▶ Same DP subproblems
- ▶ Running time can be reduced to  $O(n^2)$  using *quadrangle inequality*
  - ▶ Intuitively: When adding more weight in right subtree, optimal root cannot move left.
  - ▶ Requires to remember  $r$  for each subproblem
- ▶ For original alphabetic tree problem, can actually find optimal tree in  $O(n \log n)$  time with a much more intricate algorithm

## 12.7 Edit Distance

# Edit Distance

Our last DP application here: (algorithmic foundation of) `diff`!

- ▶ `diff` is a classic Unix tool to compare two text files
- ▶ routinely used in version control systems such as `git`
- ▶ abstract problem: measure how different two strings are
  - ▶ We've seen *Hamming distance* ...  
But how to deal with strings of different lengths?
  - ▶ how to match common parts that are far apart?
  - ▶ `diff` works line-oriented, but we will formulate the problem character oriented

## Edit Distance Problem

- ▶ **Given:** String  $A[0..m)$  and  $B[0..n)$  over alphabet  $\Sigma = [0..\sigma)$ .
- ▶ **Goal:**  $d_{\text{edit}}(A, B) =$  minimal # symbol operations to transform  $A$  into  $B$   
operations can be insertion/deletion/substitution of single character

# Edit Distance Example

Example: edit distance  $d_{\text{edit}}(\text{algorithm}, \text{logarithm})$ ?

algorithm  
logarithm

0123456789  
al · gorithm  
- |+|X|||  
· logarithm

# Edit Distance by DP

1. **Subproblems:**  $(i, j)$  for  $0 \leq i \leq m, 0 \leq j \leq n$  compute  $d_{\text{edit}}(A[0..i], B[0..j])$
2. **Guess:** What to do with last positions? (insert/delete/(mis)match)
3. **Recurrence:**  $D(i, j) = d_{\text{edit}}(A[0..i], B[0..j])$

$$D(i, j) = \begin{cases} i & \text{if } j = 0 \\ j & \text{if } i = 0 \\ \min \begin{cases} D(i - 1, j) + 1, \\ D(i, j - 1) + 1, \\ D(i - 1, j - 1) + [A[i - 1] \neq B[j - 1]] \end{cases} & \text{otherwise} \end{cases}$$

- $\rightsquigarrow O(nm)$  space and time  
space can be improved to  $O(\min\{n, m\})$  by remembering only 2 rows or columns
- An optimal *edit script* can be constructed by a backtrace

# Generalized Edit Distances

- ▶ The variant we discussed is also called *Levenshtein distance*
  - ▶ all operations have cost 1
- ▶ we can directly give each of the following its **own cost** in our DP algorithm
  - ▶ deleting an occurrence of  $a \in \Sigma$
  - ▶ inserting an  $a \in \Sigma$
  - ▶ substituting  $a \in \Sigma$  for  $b \in \Sigma$
- ▶ Extensions of the algorithm can support:
  - ▶ **free** insert/delete at beginning/end of a string
  - ▶ *affine gap costs*, i. e., inserting/deleting  $k$  **consecutive** chars costs  $c \cdot k + d$  for constants  $c$  and  $d$
- ▶ extensions widely used to find approximate matches, e. g., in DNA sequences
  - ~~> *Algorithms of Bioinformatics*

# Dynamic Programming – Summary

- 1. Subproblems
