Tutorial 1 for COMP 526 – Applied Algorithmics, Spring 2021

Problem 1 (Mathematical induction)

Given a sequence of numbers T(n) defined recursively by

$$T(n) = \begin{cases} 3, & \text{for } n = 0; \\ T(n-1) + 4, & \text{for } n \ge 1. \end{cases}$$
 (1)

- a) Compute the first 6 elements of T(n), i.e., T(0), T(1), T(2), T(3), T(4), and T(5).
- b) Make an educated guess about the general pattern that this sequence follows. Write this guess as a *closed form* for T(n), i.e., a formula for T(n) without recursive reference to T.
- c) Now formally prove the correctness of your guess using mathematical induction.

Problem 2 (Decreasing potential method)

There are two integral¹ parts of integer division: the quotient and the remainder. For two integers n, k > 0 the quotient (or result) of the integer division "n div k" is defined as the largest integer m with $m \cdot k \leq n$. The remainder of the division is defined as $r = n - m \cdot k$. Note that $0 \leq r < k$. The value r is also known as the result of the modulo operation, written " $r = n \mod k$ ".

Example: $10 \text{ div } 3 = 3 \text{ and } 10 \text{ mod } 3 = 1, \\ 13 \text{ div } 5 = 2 \text{ and } 13 \text{ mod } 5 = 3.$

Apply the decreasing potential method to prove that the following function Mod(n, k) always terminates when called with parameters $n \in \mathbb{N}$ and $k \in \mathbb{N}$, where $\mathbb{N} = \{1, 2, 3, \ldots\}$.

```
procedure Mod(n, k)

// Input: positive integers n, k.

// Output: value of n \mod k.

t:= n

while t \ge k

t := (t - k)

end while
```

return t

¹pun intended
